

PHINS — Israel (IL) Pitch: Executive Summary

Audience: Investors evaluating PHINS's Israel launch market.

Companion: Live, adjustable figures are in the PHINS Scenario Lab on the pitch dashboard (`/pitch-dashboard.html`). This summary is intentionally qualitative; all quantitative TAM, ceded-premium, and margin figures should be read from the live model, where public data is locked and PHINS assumptions are adjustable.

Why Israel first

Israel is the strongest first narrative for a digital-first severity product:

- **High home-care orientation.** Care delivery skews toward home and community settings, which fits a digital-first, severity-triggered benefit and marketplace orchestration layer.
 - **Large private long-term-care (LTC) penetration.** A substantial private LTC in-force base demonstrates established willingness to pay for protection beyond the public system.
 - **Visible public spend.** A clear public expenditure baseline makes the protection gap legible to regulators, partners, and customers.
- Together these create a credible launch market where PHINS can enter as a top-up and orchestration layer rather than as a public-system replacement.

The product thesis

PHINS should sell a **severity layer**, not a generic disability promise:

- An objectively severe, permanent **3+ ADL** trigger keeps the product underwritable and reinsurable.
- The health wallet is the checkout and reimbursement center; suppliers are controlled, network-governed participants.
- Coverage-aware ranking (not cheapest-only) considers coverage fit, SLA, clinical suitability, and fraud risk.

Regulatory & actuarial posture

- Israel is one of three candidate first-filing jurisdictions (IL · CA · US).

PHINS's actuarial stack (mortality/disability tables, lapse, IFRS-17-style projection, IBNR, and integrity-hashed valuations) supports an Appointed Actuary review and investor diligence.

- The platform's data-integrity backbone — append-only, hash-chained ledger with reconcilable wallet, settlement, and reserve views — is designed so every balance is reproducible from postings.

Data integrity (why the numbers can be trusted)

This pitch is produced on a platform whose core invariant is that **every** balance and decision is reproducible from append-only, hash-chained state, and derived AI/BI layers may recommend but never post^{**}. Public evidence and PHINS scenario assumptions are kept separate by design, so the model can be stress-tested without corrupting the underlying statistics.

For the full architecture and optimization detail, see the AI & BI Optimization Review, Platform Data Architecture, and Global Health Marketplace Architecture, all available from the pitch dashboard's Investor Documents hub.
